- **Social Welfare:** A/Prof Adrian Aguilera, Dr Caroline Figueroa

- **Computer Scientist:** Dr Joseph Williams

DIAMANTE Study

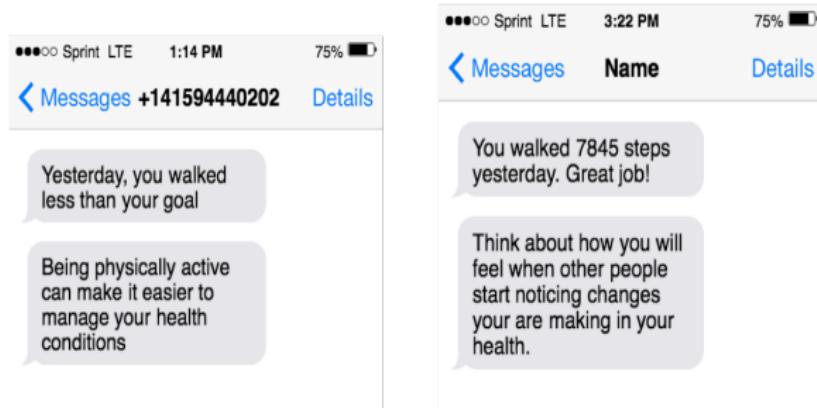

DIAbetes and Mental Health Adaptive Notification Tracking and Evaluation:
adaptive-learning and clinic-integrated mobile intervention targeting physical activity
to manage co-morbid diabetes and depression in low-income, ethnic minority patients
served in the San Francisco Health Network

Developmental Goal of DIAMANTE Study

2 different messages every day, 1 minute apart

- Learn to send better messages to patients to encourage them to walk more
- Messages are multi-component interventions, with varying levels of: (a) Time Window (when to send the message), (b) Feedback Message, and (c) Motivational Message

Design for DIAMANTE study

- The proposed design is called “Multi-Level Micro Randomized Trial”.
 - It involves multiple message components with more than 2 levels.
 - For each message component, new levels can be added through the study period.
 - The possible message levels for each participant are randomized at each sequential decision point.
 - It captures the “just-in-time” adaptive intervention purpose of mobile intervention.
 - Proximal outcome is the walking steps in next 24-hour after a message level sent.

Analysis Plan

- Data structure: longitudinal dataset with time varied interventions
- Hypothesis test: no proximal effect vs proximal effect exists
- Analysis type: generalized estimating equations
- Parameter estimator: least square
- Test statistics: Chi-squared (Large sample) or Hotelling t^2 (small sample)

Sample Size Calculation

- Power-based:
 - Number of sequential randomization
 - Effect size
 - Initial standardized effect
 - Average standardized effect
 - Trend of standardized effect over time
 - Desired power (80%)
 - Significance level (5%)
- Precision-based: desired power is replaced by desired coverage probability while effect size is replaced by margin of error.
